# Table of Contents

- Preliminaries
- Method
- Experiment
- Result
- Conclusion

# Overview

- **Problem:** Learning semi-Markovian DAGs
- **Solution:** Normalizing flow based VAE
- **Contribution**
  - ▶ A new method for learning semi-Markovian DAGs
  - ▶ A new method for learning DAGs with non-Gaussian noise

# DAG and SEM

- Directed Acyclic Graph(DAG)  $\mathcal{G} = (V, E)$  with  $V = \{1, \dots, m\}$
- Linear Structural Equation Model(SEM) is defined as

$$X_i = \sum_{j \in \text{Pa}(i)} \beta_{ij} X_j + \epsilon_i$$

where  $\epsilon_i$  is a noise variable.

- Matrix form can be written as

$$\mathbf{X} = \mathbf{A}^T \mathbf{X} + \boldsymbol{\epsilon} \quad (1)$$

where  $\mathbf{A}$  is an adjacency matrix of  $\mathcal{G}$  and  $\boldsymbol{\epsilon}$  is a noise vector.

# DAG and SEM(Cont'd)

- If  $\mathbf{I} - \mathbf{A}^T$  is nonsingular, SEM can be written as

$$\mathbf{X} = (\mathbf{I} - \mathbf{A}^T)^{-1} \boldsymbol{\epsilon} \quad (2)$$

- Usually we assume  $\boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma})$  and

$$\mathbf{X} \sim \mathcal{N}(\mathbf{0}, (\mathbf{I} - \mathbf{A}^T)^{-1} \boldsymbol{\Sigma} (\mathbf{I} - \mathbf{A})^{-1}) \quad (3)$$

# Semi-Markovian DAG

- Semi-Markovian DAG is a DAG where the noise variables have dependencies<sup>1</sup>
- The noise vector  $\epsilon$  is a semi-Markovian noise vector if

$$\Sigma \in \mathcal{W}(G) := \{\Sigma \in \mathbb{R}^{m \times m} : \Sigma_{ij} = \Sigma_{ji} = 0 \text{ if } i \notin \text{sib}(j)\} \quad (4)$$

where  $\text{sib}(j) = \{i : i \sim j \text{ in } G\}$ <sup>2</sup>

# DAG Learning

- DAG learning is a problem of estimating  $\mathcal{G}$  from  $\mathbf{X}$
- NP-hard problem<sup>3</sup>
- Score-based methods and constraint-based methods are used
- NOTEARS : conversion of DAG learning to continuous optimization problem<sup>4</sup>

$$\text{tr}(A) \tag{5}$$

---

<sup>3</sup>Chickering, Meek, and Heckerman, "Large-Sample Learning of Bayesian Networks is NP-Hard".

<sup>4</sup>Zheng et al., *DAGs with NO TEARS: Continuous Optimization for Structure Learning*.

- Variational Autoencoder(VAE) is a generative model that learns a latent variable model
- It is trained by maximizing the evidence lower bound(ELBO)

$$\mathcal{L}(\theta, \phi; \mathbf{x}) = \mathbb{E}_{q_{\phi}(\mathbf{z}|\mathbf{x})}[\log p_{\theta}(\mathbf{x}|\mathbf{z})] - \text{KL}(q_{\phi}(\mathbf{z}|\mathbf{x})||p(\mathbf{z})) \quad (6)$$

- $q_{\phi}(\mathbf{z}|\mathbf{x})$  is an approximate posterior and  $p_{\theta}(\mathbf{x}|\mathbf{z})$  is a generative model

# Normalizing Flow

- Normalizing flow transforms a simple distribution to a complex distribution<sup>5</sup>
- It is a sequence of invertible transformations  $f_t : \mathbb{R}^d \rightarrow \mathbb{R}^d$

$$z_T = f_T \circ f_{T-1} \circ \cdots \circ f_1(z_0) \quad (7)$$

- The probability density function of  $z_T$  is

$$p(z_T) = p(z_0) \left| \det \left( \frac{\partial f_T \circ f_{T-1} \circ \cdots \circ f_1(z_0)}{\partial z_0} \right) \right| \quad (8)$$

---

<sup>5</sup>Rezende and Mohamed, "Variational Inference with Normalizing Flows".

# Linear IAF

- Inverse Autoregressive Flow(IAF) is a normalizing flow that uses autoregressive transformation<sup>6</sup>
- Linear IAF is a special case of IAF where  $f_t$  is a linear transformation

$$\mathbf{z}_t = \mu_t + \sigma_t \odot \mathbf{z}_{t-1}. \quad (9)$$

- The probability density function of  $\mathbf{z}_T$  is

$$\mathbf{z}_T = \mathbf{L}(\mathbf{x}) \cdot \mathbf{z}_0. \quad (10)$$

where  $\mathbf{L}(\mathbf{x})$  is a lower triangular matrix from encoder network.

- We can use more flexible prior distribution by using normalizing flow.

# Model

Overall architecture of our model is shown in Figure below.

Figure: Overall architecture of our model

- We use the same optimization procedure as DAG-GNN<sup>7</sup>.
- The optimization procedure is minimizing the following loss function:

$$\mathcal{L}(A, W, \lambda) = -\mathcal{L}_{\text{ELBO}} + \tau \|A\|_1 + \lambda h(A) + \frac{c}{2} |h(A)|^2. \quad (11)$$

- The second term is the L1 regularization term, which encourages sparsity of the adjacency matrix.
- The third and fourth terms are the augmented Lagrangian terms.
- Gradually increasing the value of  $c$  during the training process results the acyclicity constraint to zero.

# Experiment

- We compare our method with the DAG-GNN<sup>8</sup> with random graph datasets.
- thresholding value of extracting graph as 0.3
- Erdős–Rényi random graph with 5000 samples
- Node size : 10, 20, 30, and 50 nodes
- Noise type : (Independent) Gaussian, Laplace, Exponential and (Dependent) Gaussian

---

<sup>8</sup>Yu et al., “DAG-GNN: DAG Structure Learning with Graph Neural Networks”

# Experiment(Cont'd)

- We evaluate the performance of our method using two metrics: Structural Hamming Distance (SHD), False Discovery Rate (FDR) with respect to the number of predicted edges.
- SHD measures the number of edge additions, deletions, and reversals required to transform the estimated graph into the true graph.
- FDR represents the ratio of false positives to the total number of predicted edges.
- These metrics are calculated by comparing the estimated graph with the true DAG.
- For each combination, we generate at least 5 random graphs and calculate the average metrics.

# Independent Noise

Figure: SHD with normal

Figure: FDR with normal

- In the case of independent Gaussian noise, DAG-GNN(orange) performs better than our method(blue).

# Independent Noise(Cont'd)

Figure: SHD with Laplace

Figure: FDR with Laplace

In the case of independent Laplace noise, our method(blue) performs better than DAG-GNN(orange).

# Independent Noise(Cont'd)

Figure: SHD with Exponential

Figure: FDR with Exponential

In the case of independent Exponential noise, our method(blue) performs better than DAG-GNN(orange).

# Independent Noise(Cont'd)

Predicted Edges for laplace Distribution

Figure: Number of predicted edges with Laplace

Predicted Edges for exponential Distribution

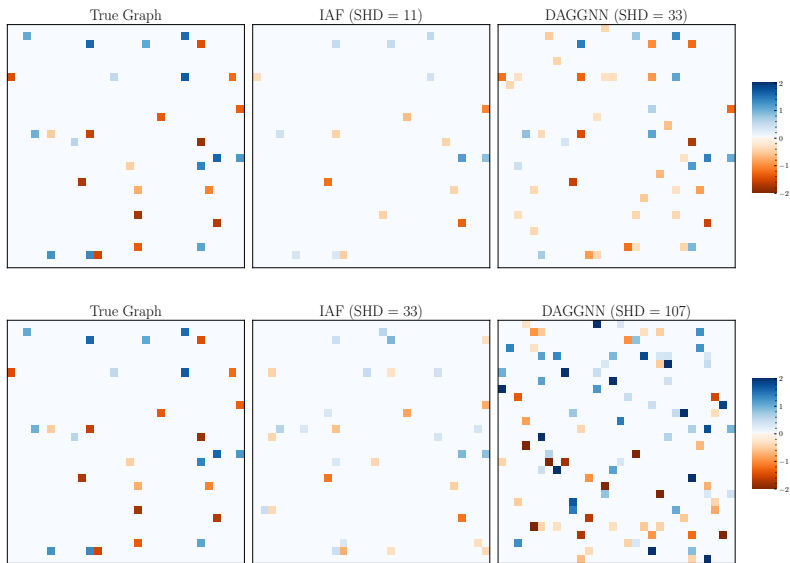

Figure: Number of predicted edges with Exponential

Considering the number of predicted edges with the SHD and FDR, our method(blue) performs better than DAG-GNN(orange).

**Figure:** Comparison of estimated graphs with Laplace(above) and Exponential(below) noise

# Dependent Noise

Proportion of bidirectional edges fixed to 0.3.

Figure: SHD with dependent Gaussian

Figure: FDR with dependent Gaussian

## Dependent Noise(Cont'd)

Proportion of bidirectional edges fixed to 0.3.

Figure: Number of predicted edges with dependent Gaussian

- In the case of dependent Gaussian noise, our method(blue) performs better than DAG-GNN(orange).
- Considering the stable number of predicted edges with the SHD and FDR, our method(blue) outperforms.

# Dependent Noise(Cont'd)

Node size  $m = 10$  : similar performance between DAG-GNN(orange) and our method(blue).

Figure: SHD with dependent Gaussian

Figure: FDR with dependent Gaussian

# Dependent Noise(Cont'd)

Node size  $m = 20$  : our method(blue) performs better than DAG-GNN(orange).

Figure: SHD with dependent Gaussian

Figure: FDR with dependent Gaussian

# Dependent Noise(Cont'd)

Node size  $m = 30$  : our method(blue) performs better than DAG-GNN(orange).

Figure: SHD with dependent Gaussian

Figure: FDR with dependent Gaussian

# Dependent Noise(Cont'd)

Node size  $m = 50$  : our method(blue) performs better than DAG-GNN(orange).

Figure: SHD with dependent Gaussian

Figure: FDR with dependent Gaussian

# Number of predicted edges

Figure:  $m = 10$

Figure:  $m = 20$

Figure:  $m = 30$

Figure:  $m = 50$

# Conclusion

- Proposed a method to learn the structure of a semi-Markovian DAG using a flow-based VAE.
- Conducted experiments on simulated data and compared the performance of our method with that of DAG-GNN.
- Our method outperforms DAG-GNN in terms of both SHD and FDR metrics, especially when the noise variables have a dependent structure and when the size of the graph is large.
- In terms of the number of predicted edges, our method results in fewer edges than DAG-GNN while maintaining the same or better level of SHD and FDR.

# Conclusion(Cont'd)

- However, contrary to our initial expectations, the lower triangular matrix  $\mathbf{L}$  learned in the IAF layer did not capture the covariance matrix of the actual noise variables.
- This seems to be due to the entanglement problem in the latent space, and resolving this issue remains a future research task.
- If the full covariance matrix of the noise variables could be found, it could be possible to directly identify bidirectional edges in the graph, enabling more accurate learning of the semi-Markovian graph.
